

Antibody - Antigen Reactions: ABO and D typing Antibody screening and identification

To cover:

- Basics of antigen/antibody reactions
- Why is the ABO group so special?
- D antigen it's complicated!
- Antibody screen
- Antibody identification
- All you need to know for the workshop!

An antigen

- An antigen can be defined as a substance that, when introduced into the circulation of an individual lacking that antigen, can stimulate the production of a specific antibody
- The antigenic determinant, which is more correctly termed an epitope, is the antibodybinding portion of the antigen

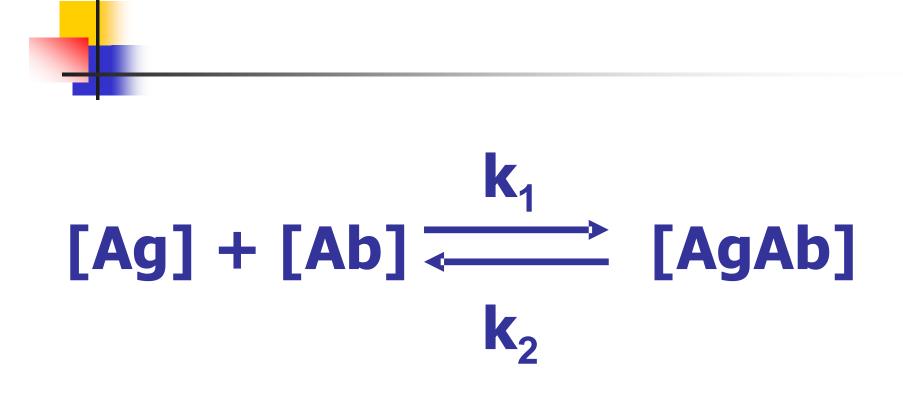

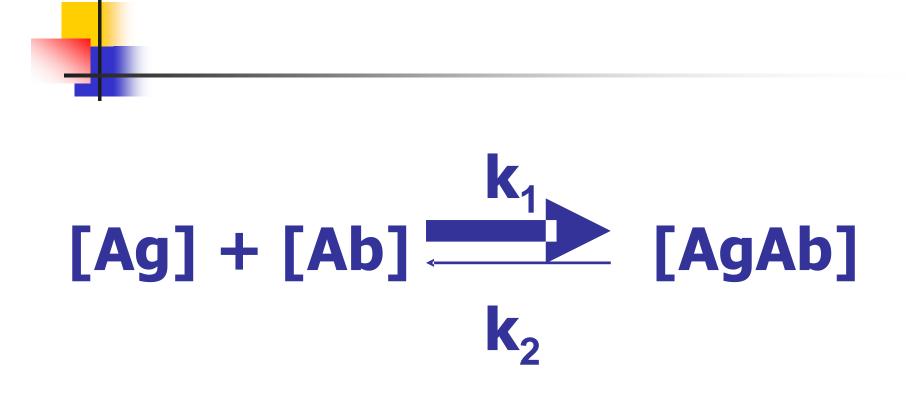

An antibody

An antibody can be defined as a serum protein (i.e. an immunoglobulin with specific antigen binding sites) produced as a result of the introduction of a foreign antigen, that has the ability to combine with (and, in many cases, destroy) the cells carrying the antigen that stimulated its production

The Law of Mass Action governs antigen antibody reactions

Nature of antigen-antibody reactions

Non-covalent bonds

The bonds that hold the antigen to the antibody combining site are all non-covalent in nature. These include hydrogen bonds, electrostatic bonds, Van der Waal's forces and hydrophobic bonds. Multiple bonding between the antigen and the antibody ensures that the antigen will be bound tightly to the antibody.

Reversibility

Since antigen-antibody reactions occur via noncovalent bonds, they are by their nature reversible. Antibody/antigen reactions in vitro take place in two distinct phases.

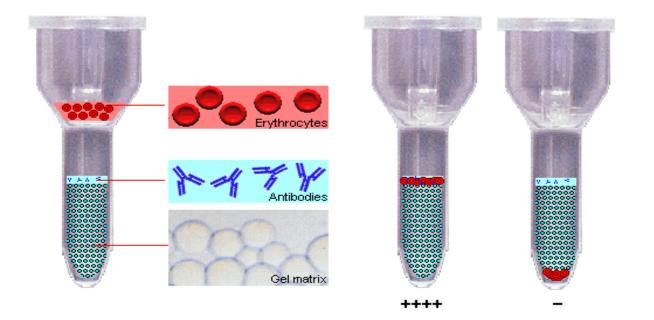

Sensitisation (antigen and antibody combine)

Agglutination (the way in which antigen/ antibody reactions are observed)

One example of agglutination ie column technology

Principle of the Gel Test

IMMUNOBASE-DIAMED

Factors affecting antibody/antigen reactions

- Ionic strength
- Incubation time
- Temperature
- Number of antigen sites (on red cells)
- Proximity of red cells
- pH
- Antigen and antibody concentration
- Antibody affinity

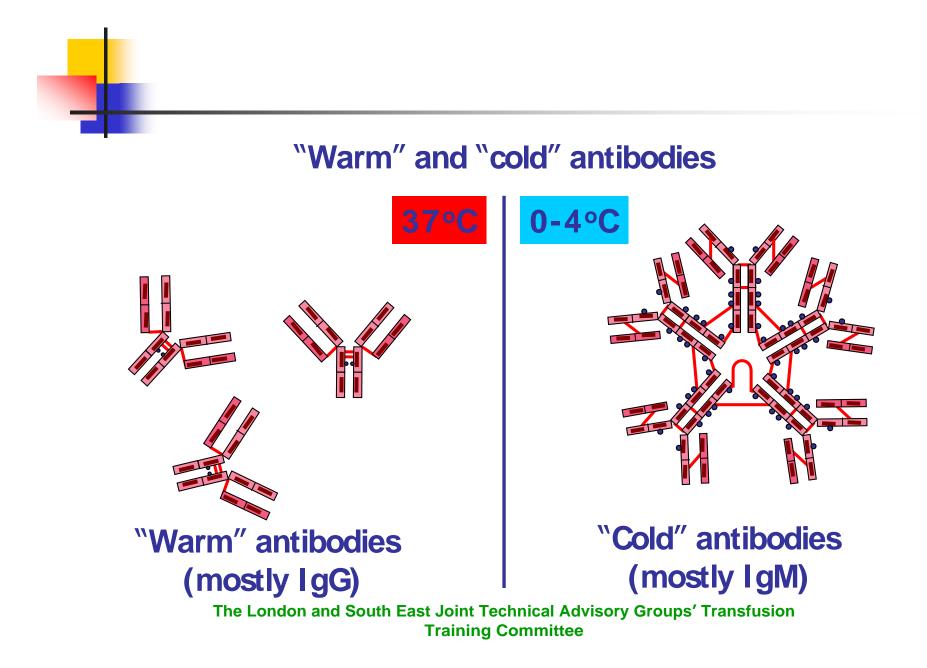

Ionic strength of the medium

- Lower ionic strengths increase the likelihood of a successful approach of a positively charged immunoglobulin to the antigen on the red cell surface, as the density of the positively charged ionic cloud is reduced. Thus, the rate of association is increased
- The rate of association of antibody with antigen may be enormously increased by lowering ionic strength
- The initial rate of association between Anti-D and the D antigen is increased 1000 fold by reducing the ionic strength from 0.17 to 0.03

Incubation time

Temperature 11 -11 11

The number of antigen sites on a red cell differs from one antigen specificity to another, by the age of the individual and, even from individual to individual.

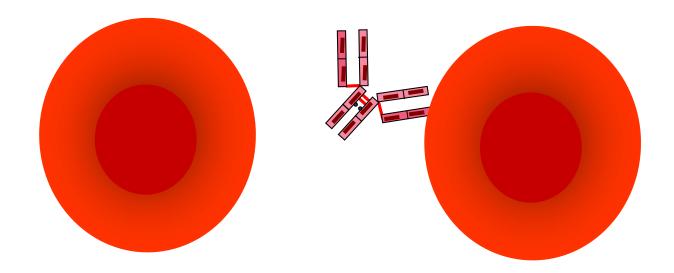

Examples

- The adult A₁ red cell has between 810 000 and 1 170 000 A₁ antigen sites per red cell.
- There are only 14 000 copies of Kidd antigens on each red cell.
- The adult A₁ red cell has between 810 000 and 1 170 000 antigen sites per red cell.
- The red cells of a newborn will only carry between 250 000 and 370 000 copies of the A₁ antigen.

Dosage

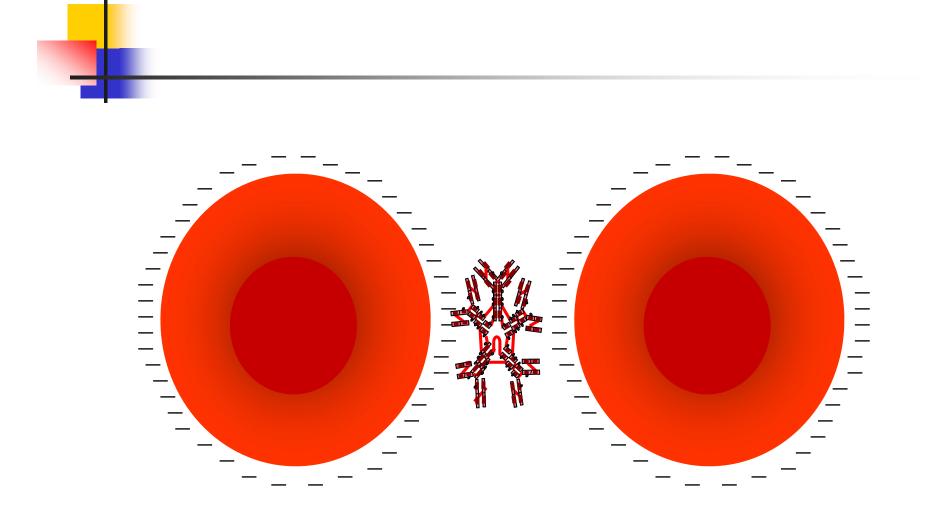

- Many antigens are expressed on the red cell more frequently if the genes are inherited in a double dose (homozygous)
- Examples of some antibodies may react more strongly or readily or only with, the "homozygous" red cells expressing the antigen

Proximity of red cells

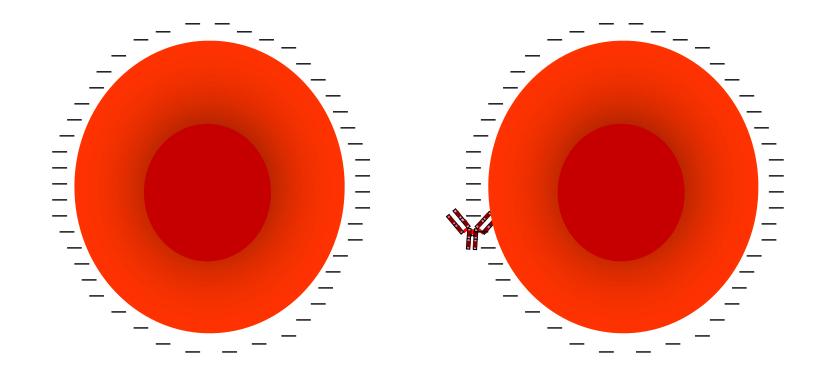

This can be brought about in several different ways

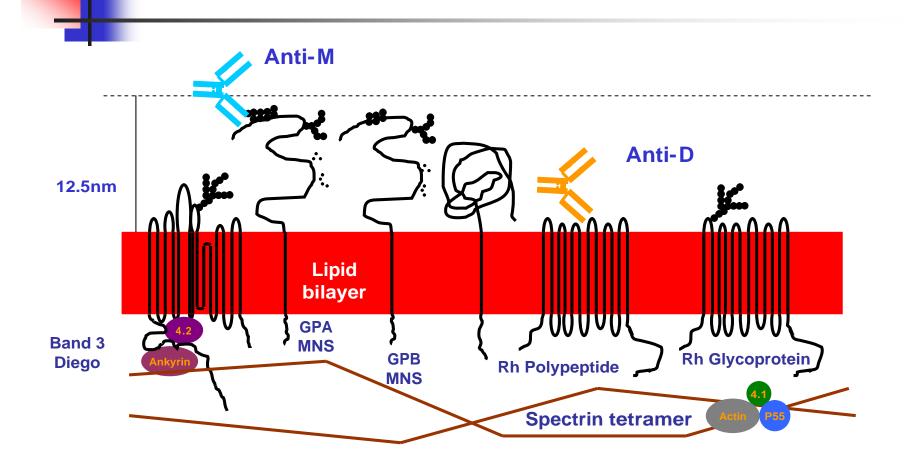

- Centrifugation will increase gravitational force and bring the red cells into closer proximity with each other by mechanical means.
- Proteolytic enzymes will bring the red cells into closer proximity with each other by chemical means.
- Anti-human globulin (AHG) will bring the red cells into closer proximity with each other by immunological means.

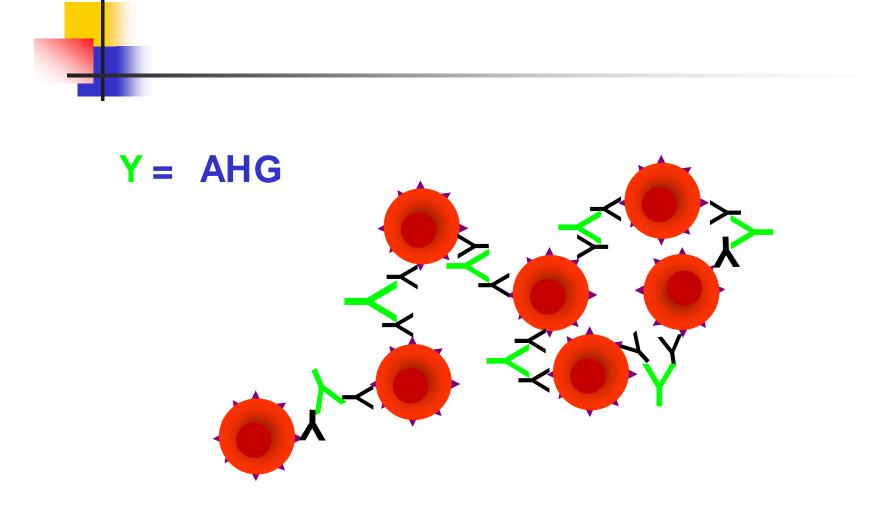

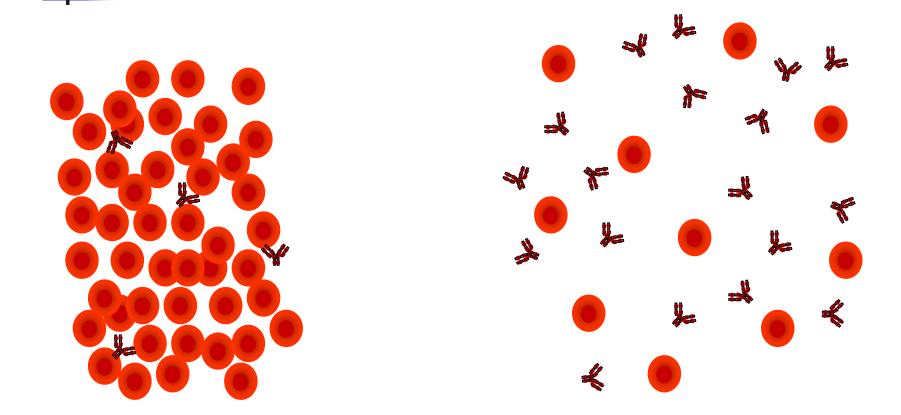

Presentation of the antigen

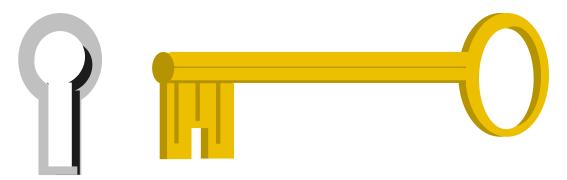

Antigen/antibody concentration

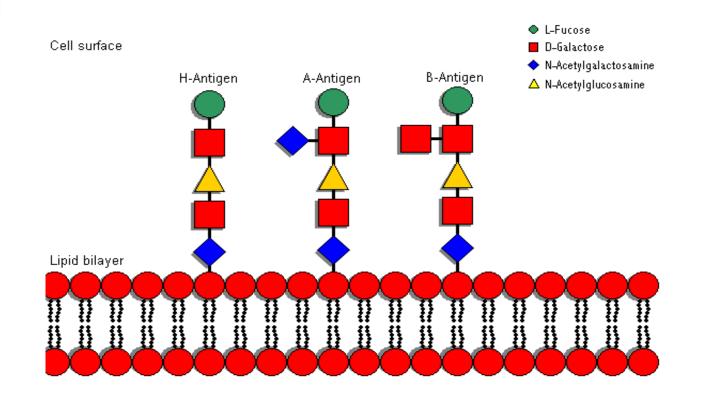

Antibody affinity

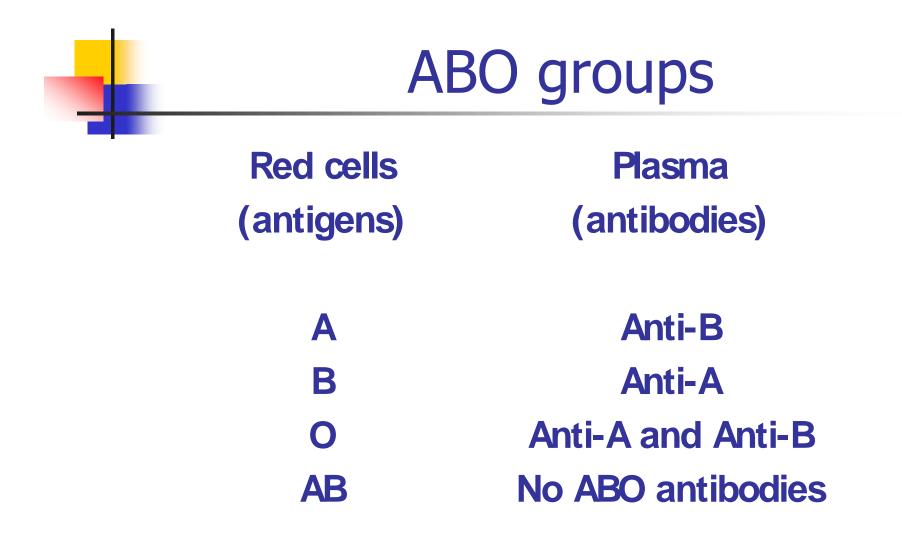

It is the sum of the attractive and repulsive forces operating between the antigenic determinant and the combining site of the antibody

ABO groups – why are they so special?

ABO antigens

	Routine ABO Typing												
Reaction of Ce	ells Tested With	Red Cell ABO Group	Reaction of Se	Reverse ABO Group									
Anti-A	Anti-B		A ₁ Cells	B Cells									
0	0	0	+	+	0								
+	0	A	0	+	Α								
0	+	В	+	0	В								
+	+	AB	0	0	AB								

D typing – it's complicated!

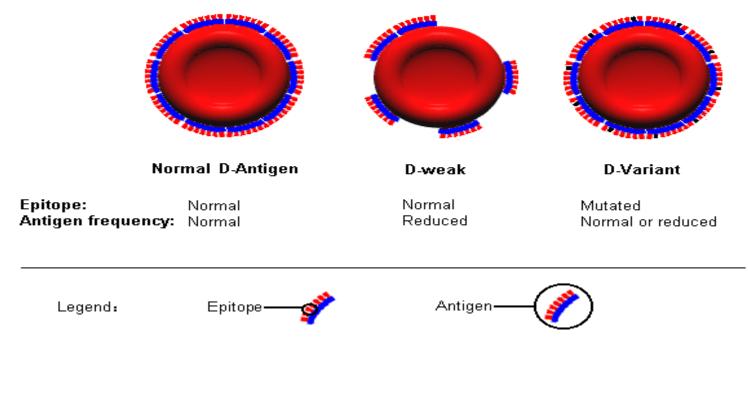

The D antigen

Most individuals are D positive or D negative

 An individual may have a weak D antigen (previously known as D^u)

 An individual may have a partial D antigen (previously known as a D^{variant})

RhD

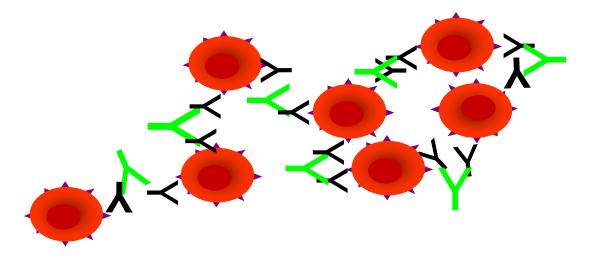

The antibody screen

- The antibody screen is a serological technique designed to detect the presence of any clinically significant antibodies (excluding ABO) present in a sample.
- A clinically significant antibody is able to bind to its corresponding antigen in vivo, sensitising the red cell. It may initiate activation of complement, and is generally associated with shortened survival of transfused red cells and/ or haemolytic disease of the newborn/fetus.

Indirect antiglobulin test (IAT)

 Clinically significant antibodies in vitro are detected by the indirect antiglobulin technique (IAT) at 37°C

Antibody screening cells must express the following antigens:

• C, c, D, E, e, • K, k, • Fy^a, Fy^b, Jk^a, Jk^b, S, s, M, N, ■ **P**₁,

Antibody Identification

- Once an antibody has been detected it should be identified as quickly as possible to ascertain its potential clinical significance
- When an antibody is detected in the antibody screen, crossmatch compatible blood should not be issued until:
 - The antibody has been positively identified and
 - If the antibody is clinically significant, units phenotyped and found antigen negative for the appropriate antibody have been obtained

Antibody specificity

 Current pre-transfusion guidelines state: `The specificity of an antibody should only be assigned when it is reactive with at least two examples of reagent red cells carrying the antigen and non-reactive with at least two examples of reagent red cells lacking the antigen '

In order to meet this criteria more than one identification panel may be necessary

Antibody exclusion

It is essential when one antibody has been identified, that the potential presence of another masked antibody has not been overlooked

 Antibody exclusion is an important part of antibody investigative work and should always be performed
